TITLE: Measurement of reflectivity in semiconductors in the plasma edge region

SOURCE: Przeglad elektroniki, no. 10, 1965, 477-487

TOPIC TAGS: semiconductor research, semiconductor plasma, semiconductor carrier, light reflection coefficient, optic property, optic measurement, cadmium selenide, indium compound, antimonide

ABSTRACT: After a brief discussion of the importance of optical investigations of semiconductors, the method of measuring the coefficient of reflectivity in semiconductors is described and its merits pointed out. The optical properties of semiconductors in the region of plasma edge are then discussed. The dependence of the index of refraction and the coefficient of extinction on wavelength of incident radiation and the semiconductor parameters is investigated analytically; the analysis shows that the reflection coefficient has a minimum (plasma minimum) when the frequency of incident radiation is close to the plasma frequency and then it rapidly increases to unity as the refractive index tends to zero giving the so-called plasma edge. The analysis shows that for a given semiconductor the position of plasma edge depends on the concentration of current carriers thus making it possible to measure easily the plasma edge. Further analysis shows that the plasma edge undergoes splitting in the presence of external magnetic field and the difference between the positions of the two new minima is equal to the

Pilarczyk J., Staub F., Sniegon K. The Welding of Heat-Resisting Steels.
"Spawanie stali zarośpionych". Przeglad Spawalnictwa, No. 2,
1954, pp. 20-31, 13 figs., 5 tabs.

POL.

The authors review the results of gas and arc welding on heat-resisting steels by means of ES24-18 electrodes of past and present manufacture, and ES18-8-6 electrodes. The experiments revealed that 1) the arc method, since it provides a weld of superior mechanical strength, is more suitable for welding KNS-12 heat-resisting steel; 2) joints made with the use of ES18-8-6 electrodes are only slightly less sound than joints made by using the more expensive type of ES24-18 electrode; 3) the resistance to high temperatures of welds made by either of these two methods is not inferior to that of the KNS-12 steel itself; 4) the strength of the welds is lower than that of the parent material, a fact which should, by introducing correction factors given in an accompanying table, be allowed for in the constructions.

Sniegur, K. The Welding of Sheets Electroplated with Non-Corrodible Steel.

POL.

"Spawanie blach platerowanych stali 'kwasoodpornej'. Przeglad Spawalnictwa, No. 2, 1954, pp. 31-30, 25 figs., 1 tab.

The author deals with the welding of sheets electroplated with non-corrodible steel by the most satisfactory methods, suitable for the fabrication of sheets in which the electro-deposited coating is in thickness not less than 0.6 millimetres. Arc welding technique, which gives tight joints with good mechanical properties, is the most suitable method for such sheets. It is possible to weld sheets of a total thickness, including the coating, of even more than 12 millimetres. When making butt and fillet welds, it is essential, on the coated side, to make the weld by means of a corrosion-resistant electrode, and on the plain steel side — by means of a welding electrode. The electrodes to be used for this purpose are the grade E518-8-2, acid-resistant; cross-welds which are less resistant to corrosion should be carefully avoided. The author suggests, with a view to slowing down the rate of corrosion, grinding the surface of the weld on the coated side until it becomes level with the surface of the sheet, and the use of a detergent for removing tarnishes and impurities from the surface.

The author carried out experiments over the arc welding, by means of bundles of electrodes, and the automatic welding, by means of covered electrodes, of gauge boiler plates up to 50 mm. Since it was found that welds made by using bundles of electrodes reveal lower mechanical properties as a result of the presence in them of considerable gas occlusion and non-metallic inclusions, this method must be ruled out. Hand-made welds, however, made by arc welding technique, reveal satisfactory properties. Optimum results were obtained by using the automatic, covered arc welding technique.

Fractions of Coke Tar.

"Charakterystyka i właściwości wysokowrzących frakcji smoły kok-
sowniczej". Przemysł Chemiczny, No. 10, 1955, pp. 679-585, 5 figs., 3 tabs.

An investigation of several oils from high boiling fractions of coke
tar as raw materials for obtaining valuable aromatic compounds, chiefly:
pyrene, fluoranthene, and chrysene. It was found that chrysene oil is
the most suitable for this purpose. The negative influence of acid and
basic components on the proper trend of distillation of the oils investi-
gated is confirmed. New conceptions have been introduced, such as
band of the range of temperatures of boiling fractions of oil, and band
curve of distillation. Some high boiling tar fractions were investigated,
by interpreting the results obtained on the basis of data of the band
curve of distillation, of the curves of freezing and boiling points, and
of specific gravity.

PERIODICAL: Gornyy zhurnal, 1958, Nr 10, pp 19-21 (USSR)

ABSTRACT: The authors describe the method of advanced mine working used in the Gubskoye bauxite deposit, which, due to peculiar geological conditions, was waterlogged. The water-bearing layers were outcropped by a ditch, which was dug out along the deposit to a nearby stream. The water from these layers drained into the stream. This ditch removed enough water so that mining operations could start. About 2/3 of the deposit was extracted without any pumping installation being installed. There is 1 map.

AUTHOR: Bol'shutkin, D. N.; Leont'yeva, A. V.; Snigirev, V. G.; Startsev, V. I.TITLE: Hardness of crystalline methaneSOURCE: Fizika tverdogo tela, v. 7, no. 9, 1965, 2607-2611

TOPIC TAGS: hardness, methane, solid state

ABSTRACT: The authors study the effect of temperature on hardness and creep in polycrystalline methane at nitrogen and hydrogen temperatures. Since methane is actively dissolved by nitrogen and hydrogen, the specimens were prepared and their hardness was determined in the same hermetically sealed cryostat. The specimens were transparent without visible flaws and had a smooth horizontal surface. The hardness of the methane was determined by sinking a conical indenter into the specimen. The loading unit of the instrument consists of a metal cylinder with a weight of $P = 600$ g. On the lower section of the cylinder are three conical indenters with vertex angles of 90° located equidistantly around the cylinder. Penetration of the indenter was monitored on a cathetrometer with an accuracy of 0.01 mm. In determining the hardness, penetration of the indenter is given as $h = h_1 + h_2$ where h_1 is penetration under a load $P_1 = 10$ g, which is read on a spring indicator; h_2

Card 1/4

L 00736-66

ACCESSION NR: AP5022694

is penetration of the indenter when the load is increased from 10 to 200 g. Since the hardness H , measured by the conical indenter, is independent of the load, then

$$H = \frac{P}{\pi h^2} = \frac{P_1}{\pi h_1^2}$$

and consequently

$$H = \frac{P}{\pi \left(\sqrt{\frac{P_1}{\pi H}} + h_2 \right)^2}$$

from which the following relationship was derived for calculating the hardness

$$H = \frac{(\sqrt{P} - \sqrt{P_1})^2}{\pi h_2^2}$$

The hardness of crystalline methane is given as a function of temperature in fig. 1 of the Enclosure. Curves for argon and krypton are given for comparison (C. Trepp, *Schweizer archiv.*, Bd. 24, 191, 230, 1958). A reduction in temperature was found to reduce the creep effect in solid methane. A physical explanation is given for the effect of temperature on hardness and creep on the basis of the dislocation

TITLE: The specific heat of pure substances close to the critical point

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 48, no. 3, 1965,
981-984

TOPIC TAGS: argon, nitrogen, oxygen, specific heat measurement

ABSTRACT: The specific heat of argon of critical density was measured very carefully in temperature intervals down to approximately 0.02K. Since there are considerable discrepancies in the literature on the critical density of argon, the measurements were made at several densities close to critical. The quantity of gas in the calorimeter was determined by weighing, and the measurement error did not exceed 0.1%. Tables are given for densities of 0.533, 0.530 and 0.538 g/cm³. It was found that 0.533 g/cm³ is closest to the critical density. Curves are given for specific heat as a function of temperature for argon, nitrogen, and oxygen. The curves for argon show a sharp reduction in slope with deviations from the critical density. "The authors thank A. P. Golub', V. A. Popov, V. V. Shchekochikhina, and

Title : Frequency, non-linear and phase distortions

Periodical : Radio 2, 48 - 50, Feb 1955

Abstract : A general discussion is presented concerning the importance of frequency, non-linear and phase distortions in radio and television. Phenomena causing the above mentioned distortions are explained, and the characteristics of individual distortions are described. Diagrams.

TITLE:

Photoelectric Devices for Recording the Spectra of Luminosity of
Momentary Processes

PERIODICAL:

Tr. Komiss. po pirometrii pri Vses. Nauchno-issled. in-te metrol.,
1958, sb. 1, pp. 51-56

TEXT: The authors point out that the use of devices with photoelectric recording represents the most effective mode of measuring the radiation intensity with resolution in time. However, the photoelectrical receiver records only one spectral line or a narrow section of the continuous spectrum. If it is necessary to obtain knowledge on the entire spectrum or on certain of its sections, either the transposition of the spectrum before the exit slot of the monochromator may be accomplished (scanning), or several exit slots, i.e., the multi-channel record scheme, may be used. Two devices are described in the article, which use both of the modes of recording. One of the devices is a four-channel photoelectric spectrometer and analyzes the wide spectral region from 12,000 to

Processes

3,600 Å. The light is dispersed by a diffraction grating. The exit slots are able to single out any four lines or two lines and two sections of the background in their vicinity. The light fluxes singled out by the slots get into photomultipliers; the photocurrent is amplified and fed to oscilloscopes, the screen images of which are photographed. The oscilloscopes yield the time-variation of the intensities of the spectral lines or the sections of the continuous spectrum. The device permits the fixing of flares with a duration from 10^{-6} to 1 sec. The other device accomplishes the scanning of the spectrum by means of two channels in the regions of either 4,000-6,500 Å or 6,500-12,000 Å. The recording time of a single spectrum amounts to 2×10^{-3} - 0.1 sec. The number of spectra recorded in time sequence amount to ten. Two slots simultaneously run over the spectrum, also obtained by means of the diffraction grating. The light flux gets into the photomultiplier, and the photocurrent is fed to a double-beam oscilloscope, the screen images of which are filmed. The measurements of the temperature of spark discharges in time were carried out by means

TITLE: On the Problem of the Time Required for Establishment of Thermodynamic Equilibrium in the Plasma of an Arc Discharge (K voprosu o vremenii ustanovleniya termodynamicheskogo ravnovesiya v plazme dugovogo razryada)

PERIODICAL: Optika i spektroskopiya, 1959, Vol 7, Nr 1, pp 14-20 (USSR)

ABSTRACT: The authors measured the time required for establishment of thermodynamic equilibrium in a 5-15 A, 45 V d.c. arc burning between carbon electrodes in air at atmospheric pressure. This time was taken to be equal to the time necessary to establish equilibrium in the arc after application of a short (10-25 μ sec) pulse of 80-200 A across the arc gap. The pulses (Fig 2) were produced by discharging a 5 μ F, 300 V capacitor or using a circuit consisting of six sections, each with a $C = 0.25 \mu$ F and $L = 10 \mu$ H (the pulse generator circuit is shown in Fig 1). Establishment of thermodynamic equilibrium conditions after a pulse was taken to be that moment at which the temperatures T_{exc} , T_{vibr} and T_{rot} became equal. T_{exc} was the temperature deduced from the relative intensities of the atomic lines Fe I 5269.5 and 4325.76 Å, T_{vibr} was the temperature deduced from the ratio of the intensities of unresolved 0-1 and 1-2 CN

band edges at 4215.0 and 4197.2 Å. T_{rot} was the temperature deduced from the distribution of intensities in an unresolved 0-1 CN rotational band with an edge at 4215.0 Å. Measurements with a four-channel photoelectric spectrometer SP-64 yielded the values $T_{\text{exc}} \approx T_{\text{vibr}} \approx T_{\text{rot}} \approx 4200^{\circ}\text{K}$ before a pulse was applied; 20-25 μsec after a pulse the three temperatures became equal again at about 6000°K (Figs 3, 4). The authors conclude that this interval of 20-25 μsec is the time required for establishment of thermodynamic equilibrium conditions in the arc described above. There are 4 figures, 6 tables and 11 references, 4 of which are Soviet, 3 English, 3 Dutch and 1 French.

TITLE: Thyratron-controlled pulse source of ultraviolet radiation 17

SOURCE: Pribory i tekhnika eksperimenta, no. 2, 1965, 157-159 16

TOPIC TAGS: ultraviolet source, thyratron 13

ABSTRACT: Operation of the new ultraviolet source depends on the accumulation of an electric charge in a capacitor and a subsequent discharge through a gap whose breakdown is controlled by a thyratron (TGIL-700/25, hydrogen, 700 amp at a repetition frequency of 400 pulse/sec). A 0.1- μ f capacitor is used, and a quartz tube (4 mm in diameter, 100 mm long) serves as the discharge gap; commercial helium flows in the gap. At a repetition frequency of 50 cps, the spectrum in the 2800-500 Å region was studied, as well as the effect of helium pressure on the intensity of an He line and impurity lines. The radiation stability, characterized by the line intensity which is constant within 2-3%, was proven by measuring the reflecting power of lithium fluoride specimens in the 2300-500 Å region. Orig. art. has: 5 figures. [03]

Title : Pathogenesis, Treatment and Prophylaxis of Surgical Sepsis

Orig Pub: Tr. Saratovsk. Zootechn.-Vet. In-ta, 1956, 6, 210-216

Abstract: The treatment of animal affected by septicemia, should be etiopathogenic, consisting of local, symptomatic and general treatment. The local treatment consists of surgical procedures followed by treatment of the primary nidus. The symptomatic - by improvement and restitution of the damaged organic and systemic function. The general treatment is directed towards the infections and intoxications in the organism; towards the defense of the organs and tissues against microbial damage; towards the elevation of the organism's resistance and its immunobiological properties. Satisfactory results in septicemia are obtained with the administration of glucose with urotropine. For the reduction of acidosis the intravenous injection

SOURCE: Zoologicheskiy zhurnal, v. 45, no. 1, 1966, 125-130

TOPIC TAGS: ground squirrel, ground squirrel reproduction, disease vector, virus

ABSTRACT: In noncultivated districts of Amur-Zeya plateau, the ground squirrel (*Citellus undulatus menzbieri* Ogn.) prefers dry steppe areas, the southern slopes and dry valley meadows of mixed grass as its habitat. In general the occurrence of this rodent closely parallels the distribution of human habitation. The females produce one litter of 3-11 offspring per season. The main natural enemy of the ground squirrel appears to be *Mustela altaica*. The paper presents data on reproduction, feeding habits, burrow structure, and distribution of the ground squirrel.
